**FIELD OF THE INVENTION**

15           The present invention provides (i) a process for preparing a 2-deoxy-2-fluoro-2-methyl-D-ribonolactone derivative, (ii) conversion of the lactone to nucleosides with potent anti- HCV activity, and their analogues, and (iii) a method to prepare the anti-HCV nucleosides containing the 2'-deoxy-2'-fluoro-2'-C-methyl- $\beta$ -D-ribofuranosyl nucleosides from a preformed, preferably naturally-occurring,  
20       nucleoside.

**BACKGROUND OF THE INVENTION**

          In light of the fact that HCV infection has reached epidemic levels worldwide, and has tragic effects on the infected patients. Presently there is no  
25       universally effective treatment for this infection and the only drugs available for treatment of chronic hepatitis C are various forms of alpha interferon (IFN- $\alpha$ ), either alone or in combination with ribavirin. However, the therapeutic value of these treatments has been compromised largely due to adverse effects, which highlights the need for development of additional options for treatment.

30           HCV is a small, enveloped virus in the *Flaviviridae* family, with a positive single-stranded RNA genome of ~9.6 kb within the nucleocapsid. The genome contains a single open reading frame (ORF) encoding a polyprotein of just over 3,000 amino acids, which is cleaved to generate the mature structural and

nonstructural viral proteins. ORF is flanked by 5' and 3' non-translated regions (NTRs) of a few hundred nucleotides in length, which are important for RNA translation and replication. The translated polyprotein contains the structural core (C) and envelope proteins (E1, E2, p7) at the N-terminus, followed by the

5 nonstructural proteins (NS2, NS3, NS4A, NS4B, NS5A, NS5B). The mature structural proteins are generated via cleavage by the host signal peptidase. The junction between NS2 and NS3 is autocatalytically cleaved by the NS2/NS3 protease, while the remaining four junctions are cleaved by the N-terminal serine

10 NTP-dependent helicase activity which unwinds duplex RNA during replication. The NS5B protein possesses *RNA-dependent RNA polymerase* (RDRP) activity, which is essential for viral replication. It is emphasized here that, unlike HBV or HIV, no DNA is involved in the replication of HCV.

U. S. Patent Application (Serial No. 10/828,753) discloses that 1-(2-deoxy-2-

15 fluoro-2-C-methyl- $\beta$ -D-ribofuranosyl)cytosine (14) is a potent and selective anti-HCV agent. The original synthetic procedures (Schemes 1 – 3) are quite inefficient, with overall yields at or below 4% and are not amenable to large-scale.

What is needed is a novel and cost effective process for the synthesis of 2-C-alkyl-2-deoxy-2-substituted-D-ribofuranosyl nucleosides that have activity against HCV.

#### DETAILED DESCRIPTION

Presently no preventive means against Flaviviridae, including hepatitis C virus (HCV), Dengue virus (DENV), West Nile virus (WNV) or Yellow Fever virus (YFV), infection is available. The only approved therapies are for treatment of HCV infection with alpha interferon alone or in combination with the nucleoside ribavirin, but the therapeutic value of these treatments has been compromised largely due to adverse effects. It was recently discovered that a group of nucleosides, including 2'-deoxy-2'-fluoro-2'-C-methylcytidine (14), exhibit potent and selective activity against replication of HCV in a replicon system. However, the difficulty of chemical synthesis of this and analogous nucleosides impedes further biophysical, biochemical, pharmacological evaluations mandatory for development of clinical drugs for treatment of Flaviviridae infection.

The present invention provides an efficient preparation of nucleosides containing the 2-deoxy-2-fluoro-2-C-methyl-D-ribofuranosyl moiety **III** and **IV**, through (i) synthesis of intermediate the 3,5-protected 2-deoxy-2-fluoro-2-C-methyl-D-ribo- $\gamma$ -lactone of general structure **V**, (ii) conversion of **V** into purine and  
5 pyrimidine nucleosides of general structures of **III** and **IV**, and (iii) preparation of nucleosides of general structures of **III** and **IV** from preformed, preferably natural, nucleosides.

## PREPARATION OF THE COMPOUNDS

(i) Synthesis of 3,5-Di-O-protected-D-ribo- $\gamma$ -lactone

- 5 Wittig reaction of 2,3-*O*-isopropylidene-D-glyceraldehyde 39 (Scheme 4) with commercially available 40 affords the (*E*)-product 41 as a major product. Sharpless dihydroxylation (J. Org. Chem. 1992, 57, 2768-2771) using AD-mix- $\beta$  as a dihydroxylation reagent gives only the desired product 42 in very high yield. High yield lactonization of 42 to 2-*C*-methyl-D-arabino- $\gamma$ -lactone (46) is achieved by
- 10 HCl/MeOH treatment. Selective *O*-benzoylation of primary and secondary OH groups yields 3,5-di-*O*-benzoyl derivative 47 in high yield. Treatment of 47 with DAST or Deoxofluor, [bis(2-methoxyethyl)amino]sulfur trifluoride, under various conditions gives trace amounts of the desired 2'-fluoro-ribo- $\gamma$ -lactone 49, but mostly a mixture from which the non-fluorinated ribonolactone (48) is isolated.
- 15 However, treatment of 47 with excess, preferably three (3) equivalents, of tertiary amine, preferably diisopropylethylamine, and excess, preferably five (5) equivalents, of DAST or Deoxofluor provides 49 in ~50% yield. It was also found that using 3,5-*O*-MOM instead of benzoyl protection, the yield of 48 approaches 90%. Thus, treatment of 46 with dimethoxymethane in the presence of strong acid such as
- 20 trifluoromethylsulfonic acid affords 50, which upon reaction with DAST or Deoxofluor in the presence of base yielded 87% isolated yield of 49.

- It was also discovered that smooth fluorination can occur upon treatment of the open-chain monobenzoate 43, which can be readily obtained by selective benzoylation of 42, with DAST or Deoxofluor giving rise to the desired ethyl 2-deoxy-2-fluoro-2-*C*-methyl-3-*O*-benzoyl-4,5-*O*-isopropylidene-D-ribonate 44.
- 25 Lactonization of 44 gives only the  $\gamma$ -lactone 45. Further benzoylation of 45 affords dibenzoate 49.

Scheme 4

In one embodiment of the present invention, a method is provided for the synthesis of intermediate 49 through Reformatsky condensation of 39 with an alkyl 2-bromopropionate such as 53 (Scheme 5) in the presence of activated zinc in an ethereal solvent such as diethyl ether or tetrahydrofuran (or a mixture of the two solvents) to give 54, which is converted to 55 by oxidation. Possible oxidizing agents are: activated dimethylsulfoxide, such as a mixture of dimethylsulfoxide, trifluoroacetic anhydride or acetic anhydride (a Swern/Moffat oxidation); chromium trioxide or other chromate reagent; Dess-Martin periodinane; or tetrapropylammonium perruthenate (TPAP) with or without molecular sieves. This oxidation to provide the C-3 ketone preferably proceeds without affecting the stereochemistry at C-4.

Fluorination of 55 is performed at the 2-position using an electrophilic fluorination ("F<sup>+</sup>") in an appropriate solvent such as dimethylformamide, tetrahydrofuran, ethanol, *tert*-butanol, or diethyl ether or any combination of these solvents known to those skilled in the art (Rozen, et. al., *J. Org. Chem.*, 2001, 66, 7646-7468; Jun-An Ma and Dominique Cahard, *Journal of Fluorine Chemistry*,

2004, *in press*, and references cited therein), to afford 56. Some non-limiting examples of electrophilic fluorinating reagents are Selectfluor<sup>®</sup>, N-fluorosulfonimide (NFSI), and AcOF. Stereoselective fluorination can be achieved by using a catalyst such as an asymmetric transition metal complex catalyst as taught by Sodeoka, et al. (JP2004010555) or by other catalysts. The starting  $\beta$ -keto ester 55 may also be first converted to a ketene silyl acetal prior to fluorination (Rozen, et. al., *J. Org. Chem.*, 2001, 66, 7646-7468).

Selective reduction of the C-3 ketone 56 using triphenylsilane in the presence of a Lewis acid such as  $\text{AlCl}_3$  or in the presence of an organic acid such as trifluoroacetic acid (Kitazume, et al., *J. Org. Chem.*, 1987, 52, 3218-3223) provides two 2,3 *anti* products 57 and 58. However, by utilizing a stereoselective fluorination combined with the selective reduction, a good yield (with high diastereomeric excess) of 58 can be achieved. Benzoylation of 58 gives 44 which is converted to lactone 45 as described earlier.

Scheme 5

## (ii) Preparation of nucleosides containing 2-deoxy-2-fluoro-3-methyl-D-ribofuranosyl moiety by condensation.

A lactone such as 49 can be reduced to the corresponding sugar with DIBAL-H. After acetylation of the anomeric hydroxyl group, 59 (Scheme 12) is obtained in high yield. Condensation of 59 with silylated base (e.g., silylated *N'*-benzoylcytosine under Vorbrüggen's conditions) affords a mixture of protected anomeric nucleosides 60 and 60-a. After separation of the anomers, the desired  $\beta$ -nucleoside 14 is prepared by deprotection with metal alcoholate in alcohol, preferably NaOMe/MeOH, or methanolic ammonia.

Scheme 6

5

Compound 59 can be converted into the bromo sugar 61, (Scheme 7) which is condensed with a sodium salt of purine, e.g., sodio-N6-benzoyladenine to give the corresponding protected purine nucleoside 62. The desired free nucleoside 63 is readily obtainable by saponification.

10

Scheme 7

### 15 (iii) Synthesis from preformed nucleosides:

Using preformed nucleosides as starting materials for preparation of the desired 2'-C-alkyl-2'-deoxy-2'-fluoro-β-D-ribonucleosides has certain advantages, as the formation of anomers and their subsequent separation can be circumvented, resulting in high yields of the targeted nucleosides.

Two procedures to prepare the desired nucleoside 14 from nucleoside starting materials have been disclosed (Schemes 2 and 3). As mentioned earlier, however, these procedures also produced two undesirable products 22 and 23, the latter produced by neighboring group participation as shown in Scheme 8. The separation of the desired nucleoside 14 from the mixture is rather cumbersome. Thus, this invention prevents production of 23 using non-participating protecting group, such as THP, methyl, ethyl, benzyl, *p*-methoxybenzyl-, benzyloxymethyl, phenoxymethyl, methoxymethyl, ethoxymethyl, mesyl, tosyl, trifluoroacetyl, trichloroacetyl, at the 3'-OH group.

10

Scheme 8

An example is shown in Scheme 17. When *N*<sup>4</sup>,5'-O-dibenzoyl-3'-O-mesyl-2'-deoxy-2'-C-methyl-β-D-arabinofuranosylcytosine (64) is treated with DAST or Deoxofluor, the desired fluorinated product 65 is obtained in 54% yield along with the olefin 66 in 39% yield. As expected, no unfluorinated cytidine derivative 67 is formed in detectable amounts. There are several ways to de-protect 65 to 14. An example is shown in Scheme 9 that requires a double inversion of the 3'-configuration.

20

## Scheme 9

When the 3'-O-substituent is a non-participating and non-leaving group, such as methoxymethyl (MOM), methyl, benzyl, methoxybenzyl or tetrahydropyranyl, the intermediate is fluorinated more effectively than 64.

The following examples are presented to illustrate the present invention but are not to be limited thereto.

**Experimental:** 2,3-O-Isopropylidene-D-glyceraldehyde (39) is prepared by literature procedures (Organic Synthesis, Annual Volume 72, page 6; J. Org. Chem. 1991, 56, 4056-4058) starting from commercially available protected D-mannitol. Other reagents, including 40 and AD-mix- $\beta$ , are from commercial sources.
